Abstract

Background: Open inquiry-based learning (IBL) that aims to foster higher-level thinking, is defined by students formulating their own questions and learning through exploration. The present study aimed to summarize the breadth of metrics used to evaluate health professions trainees in open IBL curricula.

Methods: We conducted a scoping review to identify publications detailing trainee outcomes in open IBL initiatives in health professions education. We queried five databases and included studies which described interventions with five phases of IBL (orientation, conceptualization, investigation, conclusion, and discussion). We completed abstract and full text reviews in duplicate. Data were collated and summarized.

Results: From 3030 record, 21 studies were included in the final extraction (k = 0.94), with nine involving physician trainees and twelve involving nursing trainees. Three studies used validated data collection tools to measure student inquiry behavior, and a single study used a validated data collection tool to measure critical thinking abilities. Most studies (n = 11) reported trainee self-reported satisfaction or perceived gain of skills as the primary outcome. All four studies using validated tools reported high scores in inquiry behaviors at the end of the curriculum and results on critical thinking skills were mixed. One study collected serial data, while remaining studies collected pre-post or post-only data.

Conclusion: IBL has the potential to cultivate a climate of curiosity among health professions learners. However, studies have relied heavily on subjective outcomes. Limited studies reported standardized measures of inquiry behaviors suggest favorable results. Curriculum innovations using IBL could make use of existing tools to better understand their impact on students' inquiry-oriented skills.

Résumé

Contexte: L'apprentissage libre par le questionnement, qui vise à favoriser une réflexion de haut niveau, se définit par le fait que les étudiants formulent leurs propres questions et apprennent par l'exploration. La présente étude visait à faire l'inventaire des méthodes utilisées pour évaluer les étudiants des professions de la santé dans les programmes qui ont recours à l'apprentissage libre par le questionnement.

Méthodes: Nous avons effectué une étude une revue exploratoire pour recenser les publications traitant des résultats des étudiants inscrits dans des programmes de formation dans une professionde la santé qui appliquent la méthode de l'apprentissage libre par le questionnement. Nous avons interrogé cinq bases de données et inclus les études qui décrivaient des interventions portant sur cinq phases de l'apprentissage par le questionnement (orientation, conceptualisation, investigation, conclusion et discussion). Nous avons procédé à l'examen des résumés et du texte intégral par deux lecteurs indépendants. Les données ont été colligées et résumées.

Résultats: Sur 3030 documents, 21 études ont été incluses dans l'extraction finale (k=0,94), dont neuf concernaient des étudiants en médecine et douze des étudiants en sciences infirmières. Les auteurs de trois études ont utilisé des outils de collecte de données validés pour mesurer le démarchede recherche des étudiants, et ceux d'une seule étude ont employé un outil de collecte de données validé pour mesurer les capacités de réflexion critique. La plupart des études (n = 11) ont avancé comme résultat principal la satisfaction des étudiants ou l'amélioration ressentie de leurs compétences. Les quatre études réalisées à l'aide d'outils validés ont fait état de scores élevés en matière de démarche de recherche à la fin du programme, tandis que les résultats concernant les capacités de réflexion critique étaient mitigés. Dans l'une des études, les données avaient été recueillies de façon longitudinale et dans les autres, avant et après ou seulement après.

Conclusion : L'apprentissage par le questionnement a le potentiel de cultiver la curiosité chez les apprenants des professions de santé. Cependant, les études recensées se sont largement appuyés sur des critères subjectifs. Des études limitées qui présentaient des mesures standardisées de la démarche de recherche des étudiants et ont montré des résultats favorables. Pour leurs innovations pédagogiques faisant appel à l'apprentissage par le questionnement, les programmes peuvent recourir aux outils de mesure existants pour mieux comprendre l'impact de cette méthode sur l'aptitude des étudiants au questionnement.

Introduction

Health professions trainees in the 21st century have access to an unprecedented amount of open access educational resources that greatly exceeds the organizational capacity of an individual's mind.¹ In response, future practitioners must be proficient in knowledge acquisition.² The Carnegie Foundation for the Advancement of Teaching highlighted the need to incorporate habits of inquiry and improvement in the 2010 Call for Reform of Medical Education as a learning strategy to optimize proficiency in knowledge acquisition.³ To meet the evolving needs of trainees and to foster greater student curiosity as the foundation for learning, inquiry-based learning (IBL) has emerged as an appealing educational strategy.

IBL focuses on learner driven acquisition of knowledge through development of inquiries, and hypothesis generation. This differs from problem-based learning in that PBL is focused on learner investigation of teacher provided problems. Comparative to problem-based learning is case based learning wherein learners are provided cases around which to target their investigation and research. Through exclusion of these other teaching methods and focusing only on open inquiry, we attempt to distinguish the specific benefits of pure trainee inquiry learning and consider how this can be incorporated in areas of health profession that involve mature learners such as post-graduate medical education and nursing education.

Educational philosopher John Dewey, a prominent education reformist in the early 20th century laid the foundation for inquiry as a central focus of science education, and Jerome Bruner pioneered the inquiry-based instruction in science curricula⁴ in the 1950s. The theory behind IBL is the constructivist, learner-driven active process of knowledge acquisition. Students formulate hypotheses and make observations in order to construct their knowledge.⁵ While descriptions of IBL vary widely in the literature, the framework can be divided into five general phases:⁵

- 1. Orientation: the topic is introduced, and the student creates a problem statement,
- Conceptualization: the student develops an open question pertaining to the problem, and generates a hypothesis,
- Investigation: the student explores or observes, they may even experiment, and interpret their findings,

- Conclusion: the student reviews the problem, hypothesis, and their interpretation of the findings to consider whether their question has been answered, and,
- 5. Discussion: the student communicates their findings to others (external) and reflects upon successes and areas for improvement within the inquiry process (internal).

While the IBL curriculum design has evolved and taken many forms since Bruner's initial model, the core foundation of student-directed epistemic curiosity has been consistently aimed at encouraging active participation, and improving scientific literacy.⁵ Studies in higher education have found that IBL can hone students' analytical and critical thinking abilities,⁶ and may improve students' overall academic performance compared to a traditional lecture-based curriculum.⁷

IBL has been variably classified and subdivided in the literature. Aditomo et al. grouped IBL curricula based on assigned tasks that include: scholarly research (students formulate questions and collect empirical data to address them), simplified research (students formulate question but only perform some aspects of data collection or analysis), literature-based research (no empirical data collection), and applied research (similar to simplified, though focused on practical issues and "real-world" problems).8

In some cases, IBL has been considered as overlapping or else an umbrella term encompassing problem-based learning (PBL).⁶ Some have sub-classified IBL based on the roles and responsibilities of teachers and students:⁹

- 1. Structured inquiry (e.g. PBL) teachers provide a problem and an outline for addressing it,
- Guided inquiry teachers provide questions to stimulate inquiry however students are selfdirected in the investigation, conclusion, and discussion, and,
- Open inquiry students develop questions themselves, and are self-directed in investigation, conclusion, and discussion.

While there have been apparent benefits of IBL in higher education, particularly with regards to fostering inquiry behavior, the outcomes of an IBL curriculum in health professions education are yet to be fully elucidated. In this scoping review, we examine the published literature

exploring student outcomes in inquiry-based learning curricula in health professions training. We aim to describe the extent of existing literature in this area, to characterize study designs and outcomes, and to identify gaps in the health professions' literature where future studies on IBL should focus.

Methods

Our study followed the framework of Arksey and O'Malley¹⁰ and the PRISMA Extension for Scoping Reviews.¹¹ Our preliminary research question explored the extent of published literature on IBL curricula in medical education. Our initial literature search revealed a scarcity of studies, and we iteratively refined this question after an extensive literature review to identify, characterize, and evaluate the scope of published studies IBL in health professions education and to identify remaining gaps in this area (Appendix A).

Terms and definitions

Whereas IBL has been variably defined and categorized in the literature, we adopted the pedagogical approach of Oğuz-Ünver & Arabacioğlu, 12 and Feletti 13 which differentiates "pure" IBL from PBL, wherein the former is founded on student-driven inquiry in a guided or open manner, and the latter on problem-solving through structured inquiry. For the purpose of this review, we have considered structured inquiry as being PBL, and guided-and open- inquiry as IBL. We also used the framework of Aditomo et al⁸ to subclassify IBL curricula based on assigned tasks.

Inclusion and exclusion criteria

Studies were eligible for inclusion if they a) evaluated an inquiry-based learning curriculum as defined above, b) studied a population of health professionals or health professions trainees, and c) reported trainee outcomes.

We excluded studies if they described multiple curricular modalities (e.g. evaluated a program with IBL, PBL and traditional lecture-based components) without providing specific evaluation of the IBL component.

Search strategy

We searched Embase, MEDLINE through PubMed, PsycINFO, CINAHL, and ERIC for eligible peer-reviewed records published up to April 20, 2021. To ensure full capture of eligible studies, bibliographies of commentaries, reviews, and book chapters were reviewed to identify additional relevant records. We consulted a librarian in the development and refinement of the search strategy, and

we iteratively refined search terms until saturation was reached. The search strategy is reported in Supplemental Digital Appendix A. All studies collected were imported into Covidence online software for screening and review.¹⁴ There were no date or language restrictions.

Review and data abstraction

After removal of duplicate studies, two reviewers independently screened all titles and abstracts against inclusion and exclusion criteria (SV and AK). Full text review was conducted independently and in duplicate. Percent agreement and Cohen's κ statistic were calculated to evaluate interrater reliability in accordance with published guidelines. All studies meeting inclusion criteria were submitted for data abstraction (SV, MY, and AK). Abstracted data points included publication date, research questions, population, study design, data collection tools and outcomes. Content was double-checked for accuracy.

Results

Study selection

A PRISMA diagram of the study selection is shown in Figure 1. Our search resulted in 3320 studies. After removal of duplicates, 2919 studies were eligible for screening. Two authors reviewed all records in duplicate with a percent agreement of 98.0% and κ statistic of 0.784 indicating substantial agreement. Twenty-one full-text records were submitted for abstraction and inclusion in the final analysis. Percent agreement for full-text review was 98% (κ = 0.939). Disagreements were resolved by discussion of rationale for inclusion or exclusion amongst the authors. The earliest record meeting inclusion criteria was from 2000.

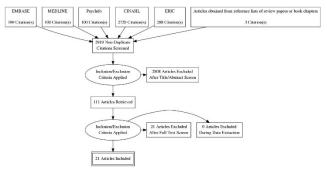

Figure 1. PRISMA diagram of study retrieval

Study design and population

Included studies are summarized in Appendix B. All 21 studies provided data on trainee outcomes, and 17 of these had this as a primary objective. Twelve studies included nursing students or licensed nurses. Nine studies included medical students, residents or fellows in their study

population. One study was done as a randomized trial; the remainder of the studies were quasi-experimental.

Data collection tools

The primary method of evaluation across the majority of the studies (n=19) was via student surveys. Only four studies used a validated survey tool to assess trainee outcomes while the remaining studies used investigator-designed surveys with no clear evidence of validation and a single study did not describe the data collection tool. Only one study collected serial data, while eight studies provided both pre- and post- intervention data, and the remainder had only post intervention data (n=13).

Trainee outcomes

Ten studies included some form of objective trainee outcomes however, in five of those studies, objective data included only course administrative information such as project poster presentations completed after the intervention, rather than assessments of behavior or competence. The majority of studies (n=11) primarily gathered subjective, self-reported outcomes through qualitative methods (e.g. Trainee perceived confidence with IBL).

Trainee Perceptions. Subjective trainee outcomes about IBL were predominantly positive across all studies (n=11). Generally, trainees felt that IBL methodology would be useful for their future career. There was a general increase in perceived skills and comfort level. Few studies (n=3) reported negative subjective student outcomes. In one study that implemented an IBL curriculum (Fin et al) trainees had difficulty understanding the concept of IBL and gained only a superficial understanding with limited application to practice, based on teacher observations. Tamayo et al described greater difficulty with and interest in the course when an IBL curriculum was used ¹⁶. Overall, there is evidence that IBL generally has a positive perception among most students but can be challenging for some to grasp.

Objective metrics. Within the few studies (n = 4) that used a validated data collection tool (see Table 1), outcomes of interest included quantifiable changes in behavior or analytical ability. All of these studies reported high scores in inquiry behaviors at the end of the curriculum and results on critical thinking skills were mixed. Wentland et al showed a significant increase in perceived skills in finding and re-reviewing evidence post IBL intervention. The Kim et al showed improved scores in all Evidence-Based Practice (EBP) activities post IBL intervention. The third study by

Magnusse et al used the Watson Glaser Critical Thinking Appraisal (WGCTA) tool to measure critical thinking skills, and found no difference in the mean WGCTA scores preand post- intervention. When separated into terciles the lowest group had a significant increase in scores while the highest group dropped with no change in the middle group. This suggested a possible benefit for trainees with the lowest baseline proficiency in critical thinking.¹⁹ Lastly, Brondfield et al, used a modified Delphi design to create and validate survey tool to measure inquiry behaviors (e.g. justifying statements with evidence, acknowledging limitations of one's own knowledge), and demonstrated that students self-graded and faculty-graded inquiry behaviors improved significant through measurements over the course of an IBL curriculum.²⁰

Table 1. Validated data collection tools in included studies

Study	Tool	Construct being measured
Magnussen ¹⁹	WGCTA (Watson Glaser Critical	Critical thinking
et al (2000)	Thinking Appraisal)	
Wentland ¹⁷	DEBPQ (Developing Evidence	Inquiry knowledge and
et al (2020)	Based Practice Questionnaire)	skills
Kim ¹⁸ et al	EBP Questionnaire	Inquiry knowledge and
(2019)	EBP Beliefs Scale	behaviours
	KAS-R (Kim Alliance Scale – R)	
Brondfield ²⁰ ,	Medical Student Inquiry	Inquiry behaviours
S et al (2019)	Behavior Assessment Tool	

Inquiry-based learning task assignments. The IBL curricula across all studies were grouped into five assigned tasks based on the Aditomo classification: Fifteen used a scholarly research method, four used a simplified research method, one used literature-based inquiry and one used applied research.

All (*n* = 15) studies using a scholarly research method reported an increase in trainee confidence, and perceived improvement in skills or benefit to their future career after the IBL learning intervention. Among the four studies that used a simplified research method, all used surveys to assess trainee outcomes. Student satisfaction was favorable, use of EBP resources increased, and students gained more comfort and interest in their chosen topic. The authors also noted a number of poster presentations from participants at scientific conferences. The lone study that used applied research also used a validated outcome tool that demonstrated a significant increase in students' perceived inquiry skills.

Discussion

This review provides a summary of the use of inquiry-based learning in health profession literature. It demonstrates evidence of the potential for IBL to cultivate learner growth and promote a climate of curiosity among health professionals. Education researchers should encouraged to investigate further the utility and benefits of IBL, the data collected in this review supports this endeavour in health profession education. With accumulation of more rigorous evidence, IBL may be incorporated into both undergraduate and post-graduate health profession courses at both individual project levels and larger course curricula levels. However, most studies rely heavily on subjective trainee outcomes, experimental research designs, and validated tools are infrequently used. Use of validated tools in future research will contribute to rigorous designs and collection of objective, reproducible data.

The existing literature has a lack of validated tools and substantial reliance on subjective perception. Within this cohort of studies, the WGCTA (Watson Glaser Critical Thinking Appraisal) measured critical thinking abilities, 19 the DEBPQ (Developing Evidence Based Practice Questionnaire), EBP Questionnaire, EBP beliefs scale, and KAS-R (Kim Alliance Scale) measured inquiry knowledge and skills, 17,18 and the tool from Brondfield et al 20 measured primarily observable inquiry behaviours. This tool showed validity for both self and faculty assessment of trainees, and may be used for serial measurements of inquiry behaviours.

Additional research into IBL can help with development of this learning strategy and incorporation of IBL into curricula. When researching IBL, studies may draw upon existing data collection devices used in other teaching modalities. Existing literature in has reviewed instruments used for evaluation of self-directed learning, team based learning and peer evaluation in team based learning.²¹⁻²³ Additionally, although self-evaluations can provide insight, Papinczak et al²⁴ demonstrated that such self-evaluations in problem-based learning is not an accurate measure of student performance.²⁴ Various validated assessment tools have been developed for problem based learning in medical education including checklists,²⁵ and objective structured clinical exams (OSCEs).26-28 Further study into the reliability and construct validity of these tools in IBL may help to establish their use in this area, and this may reduce researchers' reliance on trainee self-evaluation as the sole outcome.

These numerous studies assessing validity of evaluation tools within specific learning methods provide a basis for educators to properly design and evaluate curricula. Such literature in the realm of inquiry-based education is important to demonstrate the utility of IBL in medical education. Additionally, in order to encourage dissemination, a repertoire of validated tools for IBL should be easily accessible to educational institutions.

The IBL literature we identified focused on experimental design that involved incorporating IBL into curricula. There was a lack of literature using non-experimental, or literature-search based designs (e.g. where no empirical data collection is required). These should be explored further as potentially more feasible and widely available modality for individual studies. Most included studies introduced IBL through a research project assignment, and while this did show variable success, this framework may be difficult for widespread use based on task complexity, and a lack of available personnel and resources.

Overall, evaluating and implementing IBL in health professions education requires the development of high quality and rigorously designed studies. This may be achieved by promoting collaborative, multicenter work, focus on validated tools aimed at higher level outcomes and use of serial measurements to evaluate interventions. In addition to education, IBL may have a role in patient care and partnership with clinical researchers who may help to assess the translational potential into clinical medicine.

Future directions for IBL research include consideration of non-experimental research designs, extrapolating tools from other teaching modalities, use of validated tools when appropriate, and collaborative multicenter work.

There are limitations of this review that must be considered. Selected articles focused on IBL-exclusive curricula only, and multimodal programs that may have included an IBL component were not encompassed in the search. It is important to consider that validated tools are typically validated for specific purposes and their use in different contexts may require re-validation. Extrapolation of tools from literature would therefore need to be done with this in consideration. Additionally, due to variability in definitions, studies that used IBL format may have been categorized under different learning strategies such as problem-based or team-based learning and therefore not included in our study. Lastly, a publication bias may result

in studies with negative results being inadequately captured.

IBL methods have been effectively used in various educational settings including health profession education. This curriculum design holds promise in fostering behavioral changes for health professions trainees' ability to nurture their own curiosity and refine their scholarly aptitudes. There is a need for further study with refined data collection methods to adequately assess the potential benefits of these curricula, and novel validated tools may help advance curriculum design in this domain.

Appendix B. Summary of Included Studies

Citation	Year	Primary Research Question	Secondary Research Question(s)	Study Design	Population	Intervention	Control (if applicable	Data collection tool(s)	Outcome(s)	Strengths	Limitations (including sources of bias)
Zhang ²⁹ et al A comparison of inquiry-oriented teaching and lecture-based approach in nursing ethics education.	2019	Is an inquiry- oriented learning curriculum associated with greater perception of competency and positive attitudes in ethics in nursing education?	N/A	Quasi- experimental, two groups	Undergraduate nursing students in two nursing schools in China.	Inquiry-oriented teaching strategies (students required to identify ethical issues through literature review, analyze concepts, develop approaches, and discuss with group and facilitator)	Traditional lecture-based teaching (assigned reading, lecture via Powerpoint presentations)	Self-designed Likert-scale questionnaire measuring students' knowledge, attitudes, and competencies in nursing ethics delivered pre- and post- intervention to both groups. 36 items in 6 dimensions.	No difference in pre- investigation survey in any of 6 dimensions. Both groups scored significantly higher in 5/6 domains post- investigation. IBL group scored higher in post- investigation survey in ethical decision- making scale, and professional relationship scale. Lecture group scored higher in theoretical foundation of nursing	Two groups, multicentred study. Pre and post-investigation data available.	No validation data for survey. Outcomes exclusively based on student perception. IBL and traditional lecture not compared within centre. Institution may confound the results.
Migliore ³⁰ et al Clinical Research and Practice Collaborative: An Evidence- Based Nursing Clinical Inquiry Expansion.	2020	What is the scholarly output before and after implementation of a Clinical Research and Practice Collaborative in a nurse scientist education program?	N/A	Quasi- experimental	Nurse scientists in the Air Force Medical Service.	Implementation of Clinical Research and Practice Collaborative (CRPC), an IBL curriculum in which nurse scientists ask a clinical question in a PICOT format, perform a literature search, appraise the evidence, and implement their project.	None	Not described	ethics. Number of research initiatives unchanged after implementation of IBL curriculum (n=4). Number of research publications and posters reduced from 8 to 3 and number of EBP initiatives grew from 2 to 11 and EBP publications and posters from 2 to 12.	Pre- and post- investigation data available	Small sample size. Single institution. No description of data collection tool. Descriptive analysis only.
Magnussen ¹⁹ et al The impact of the use of inquiry-based learning as a teaching methodology on	2000	Does inquiry- based learning (IBL) enhance critical-thinking ability as measured by the Watson Glaser Critical Thinking	N/A	Quasi- experimental	Nursing students at the University of Hawaii.	Inquiry-based learning curriculum wherein students were introduced to cases and had to define their own clinical questions, complete a literature review,	None	WGCTA administered in first week of school (form A) and during final semester (form B) of the program	228 students completed pre- investigation WGCTA and 257 completed the post-test (including 150 paired scores). No difference in mean WGCTA scores pre- and post-investigation.	Pre- and post- investigation data available. Validated assessment tool.	No control groups. Single institution. No ability to address confounding

the development of critical thinking.		Appraisal (WGCTA)?				and discuss evidence to support, refute, and revise hypotheses in small- group discussion.			When separated into WGCTA terciles the lowest group had a significant increase in WGCTA scores while the highest group dropped, with no change in the middle group. Response rate of 84% in control and 87% in experimental group.	Large sample size.	from influence of other course and learning experience.
Tamayo ¹⁶ et al Evaluation of a pharmacology educational activity based on a research project: a randomized, controlled and blind analysis of medical students' perceptions.	2005	Do students involved in a research project-based experimental model of pharmacology education have more positive perceptions of their course experience than students in a traditional model of practical activity-based teaching?	N/A	Randomized, double-blind, controlled trial	Medical students at the University of the Basque Country in their 3 rd to 5 th years.	IBL curriculum Students had to identify a research issue in pharmacology, review scientific literature, generate one or more hypotheses, design and implement a study, collect and process reliable and valid data, interpret results, draw conclusions and communicate results. The overall topics were provided but students had to generate their own hypotheses and questions. Both groups had foundational lectures.	Traditional model of practical activity including laboratory and computer-assisted demonstrations of pharmacological experiments, computer-assisted bibliographic search activities and seminars. Both groups had foundational lectures.	Self-developed questionnaire assessing 18 items on a 4-point Likert-type scale. The questionnaire was delivered to students two years after the course.	No differences observed between the experimental and the control groups in any of: appropriateness of objectives, adequacy of available resources, organization, support received and enthusiasm of the teachers. IBL group reported greater difficulty and interest in the course, and greater difficulty and interest in the course, and greater perception of bring able to use their own initiative, more effort required, larger requirement for concern for the subject of the activity. IBL group felt their course to be more useful for their future profession and more positive perception of knowledge and skill acquisition.	Double-blinded. Randomized controlled trial. High response rate.	Data collection tool not validated. Only post-test available. No description of baseline characteristics of each group to assess success of randomization.
Wentland ¹⁷ et al A Nursing Research and	2020	What are the scholarly outcomes of individuals in a	What are participants' perceptions of	Quasi- experimental	Nurse scientist trainees in a Nursing Research and		N/A	Survey on reported scholarly	All respondents were female, and 85% were White. Response rates were 100% at time 1,	Use of a validated scale for perceived	Small sample size.

into Gross tyl Anatomy str Teaching Using 2020 Poster Presentations: Feasibility and	Does integration of scientific work into anatomical teaching result in a positive perception from students after stegration of cientific work ito anatomical eaching? What are the successes and difficulties with integration of the new format in anatomical teaching?	Quasi- experimental	Second-year medical students at Ulm University.	Groups of 10 students working with one body donor in an Anatomy lab to either describe anatomical findings or create a clinical question based on their findings during dissection. Students then conduct a literature search, synthesize evidence and produce either a case report or original research study to be presented in poster format to a professional audience.	N/A	Course administrative data regarding poster number and content. Self-designed post-intervention survey of students using 6-point Likert-type scale.	76 posters were created between 2019-2020. 70/76 described pathological findings in a case report format. 6/76 developed a scientific question and collected data in the form of a research study. Posters used 1-5 references, with majority collected from Google or Google Scholar and few from any other library databases. Errors were commonly noted with citation and authorship formatting. 162/373 students completed a post-course survey (43%). Students invested 2-4 hours for poster production, and 74% perceived this as burdensome (median 4/6 +/- 1.8/6)).	Mixed Methods Design.	No control group, post-test only. Single institution. Low response rate in student survey and low volume of qualitative data subject to response bias. Survey tool was not validated.

Students reported they earned competencies not only in the field of the poster's clinical (31.8%) and pathological content (24%), but also in the field of teamwork (24%) and literature search (21.7%).

In contrast, 24% of respondents indicated that they did not experience gain in any of the listed competencies. Students were unsure whether or not the project was an useful addition to the dissection course (Median 4/6; ± 1.3/6), but were positive about the experience of learning new scientific skills (Median 4/6 ± 1.2/6).

31% of the students agreed to the statement that their interest in science was increased and 46.5% of the students wished to work on scientific projects more frequently during their studies

73 codes generated from qualitative survey data, majority negative (47/73), largely related to additional workload and difficulty retrieving helpful literature.

					CANADIAN MILI	DICAL EDUCATION JC	JUNINAL 2023, 14	(2)			
Crabtree ³² et al. Improving patient care through nursing engagement in evidence-based practice.	2016	Can an evidence-based nurse scholars course improve patient care and prepare nurses to engage in EBP?	N/A	Quasi experimental	Nursing students at the Medical University of South Carolina (MUSC).	12-week, project-based course focused on teaching theory, practice and dissemination of evidence-based practice (EBP), including how to frame clinical questions, perform literature searches, analyze and evaluate evidence and translate knowledge into clinical practice. Nurses then selected a hospital policy, applied their acquired EBP knowledge and updated the policy.	No control	Pre and post self-designed survey. Course administrative data regarding poster number.	Significant increase in confidence with critically reviewing literature (p<0.001), increase in belief that EBP is necessary for nursing practice (p = 0.052), and increased interest in improving EBP skills (p=0.002). Increases in the use of EBP resources in clinical practice, including the Cochrane Database of Systematic Reviews (p<0.001), CINAHL (p<0.001), National Guideline Clearinghouse (p=0.049), PubMed (p = 0.005), and UpToDate (p = 0.018) Increased understanding of statistical concepts and study design methods (p<0.001). Successful completion of 15 projects related to nursing care and practice.	Pre and post data available	Single institution Response rate not provided. Survey tool was not validated. No control group
Durstenfeld ³³ et al. Lakin ⁴² et al A Curriculum in Quality Improvement for Interprofessional Palliative Care Trainees.	2020	Does a 4-month IBL style curriculum help learners develop a basic understanding of QI?	N/A	Quasi experimental	Palliative care fellows.	Curriculum entails 4 sessions Session 1: didactic lecture on basics of QI followed by fellows creating problem statements and aims, and brainstorming possible projects. Session 2: lecture about key tools for QI followed by fellows exploring further details of the project. Fellows expected to subsequently use a QI tool to collect data. Session 3 and 4: Groups present their project and data and receive a lecture on presentation of results and data analysis tools. In the fourth session fellows present final projects and data.	N/A	Fellows completed a curriculum evaluation tool that uses a 5- point Likert scale on their perceptions and skills sets surrounding QI before and after the course, their opinions on the course and its relevance to their clinical practice.	Course has been ongoing for 13 years, facilitated 28 teambased QI projects. 36 trainees (80%) completed the retrospective evaluation tool. Average score of 4.49 (out of 5) for effectiveness of teaching method, and average score of 4.11 for clinical usefulness of the course. Marked increase in self-reported ability and confidence in using language of QI (2.57 to 3.88). Overall increase in all evaluated measure in pre-and post-scores. Most significant improvement was in learners' ability and confidence to plan, implement and present a QI project	High response rate. Pre and post intervention data available.	No control group No objective trainee outcome measurements Curriculum evaluation tool not validated.
